# OVERVIEW OF DESIGNING THE LOAD MATCHING NETWORK FOR A POWER AMPLIFIER BY USING THE CIL WIZARD PROVIDED IN THE AMPSA ADW

Pieter Abrie  
Ampsa (Pty) Ltd.

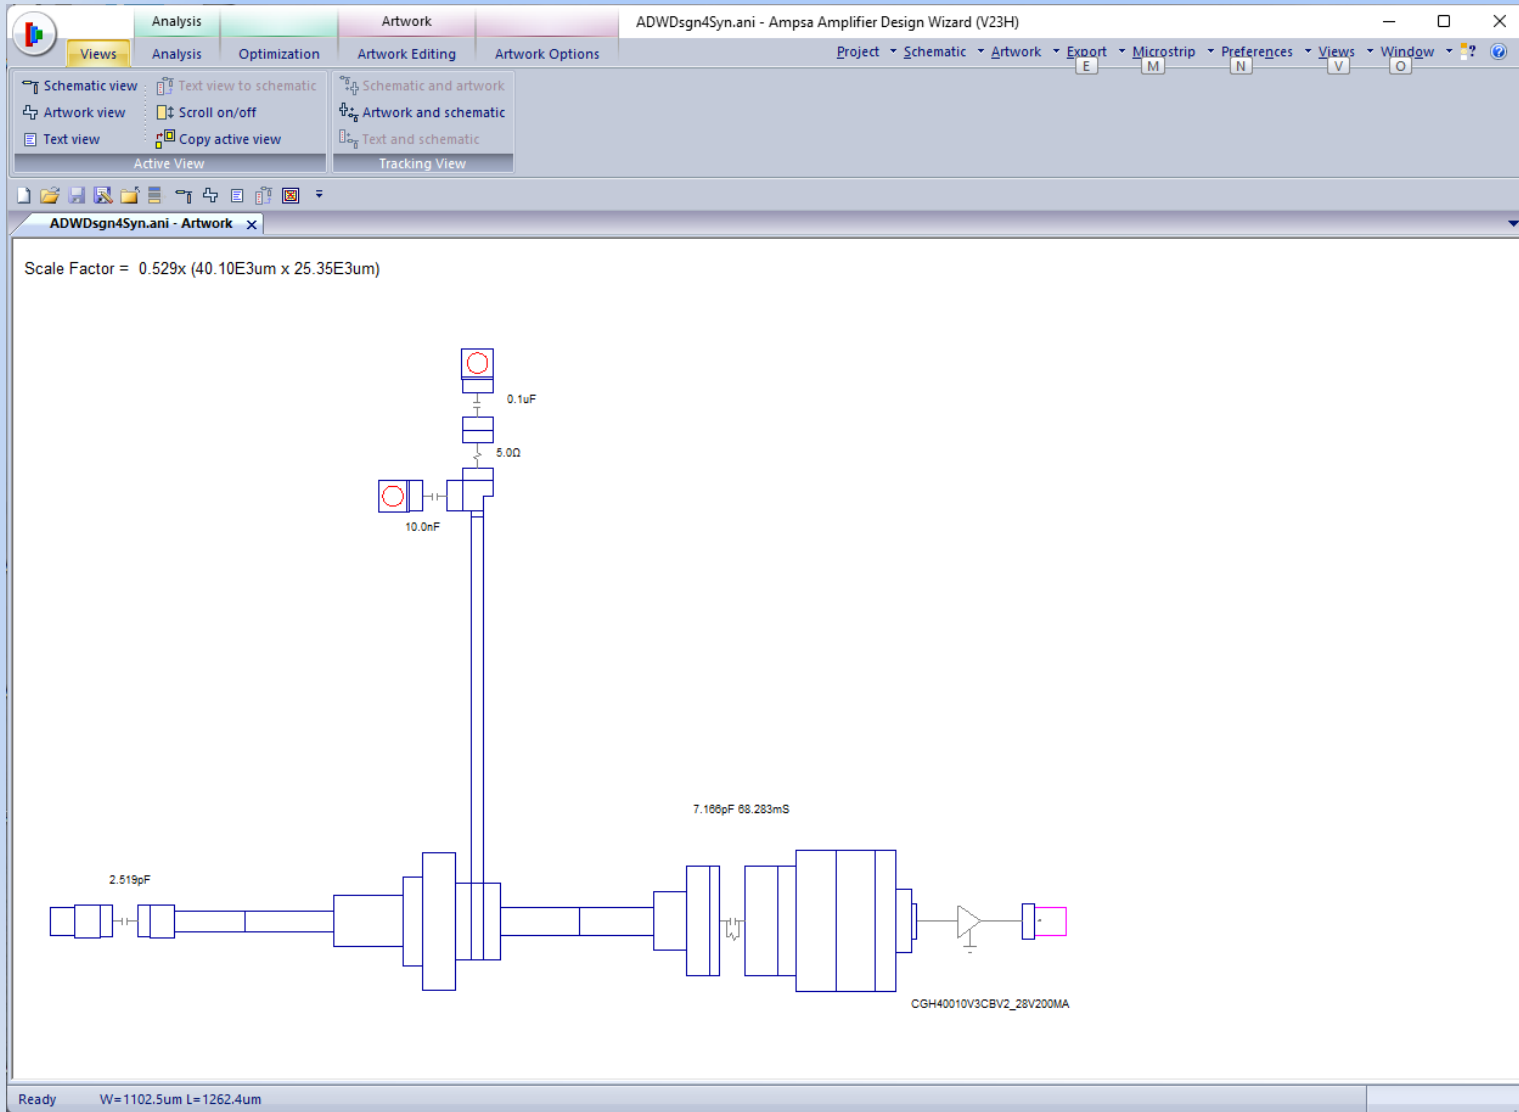

12/25/2024

The ADW is setup to design single-ended amplifiers. Note that Doherty amplifiers, balanced amplifiers, push-pull amplifiers, amplifiers with symmetrical combination networks and even some load modulated balanced amplifiers can all be converted to equivalent single-ended stages.

The Ampsa ADW CIL wizard can be used to set up a large variety of matching problems for an amplifier stage. Different classes of operation can be targeted. These include continuous modes of operation.

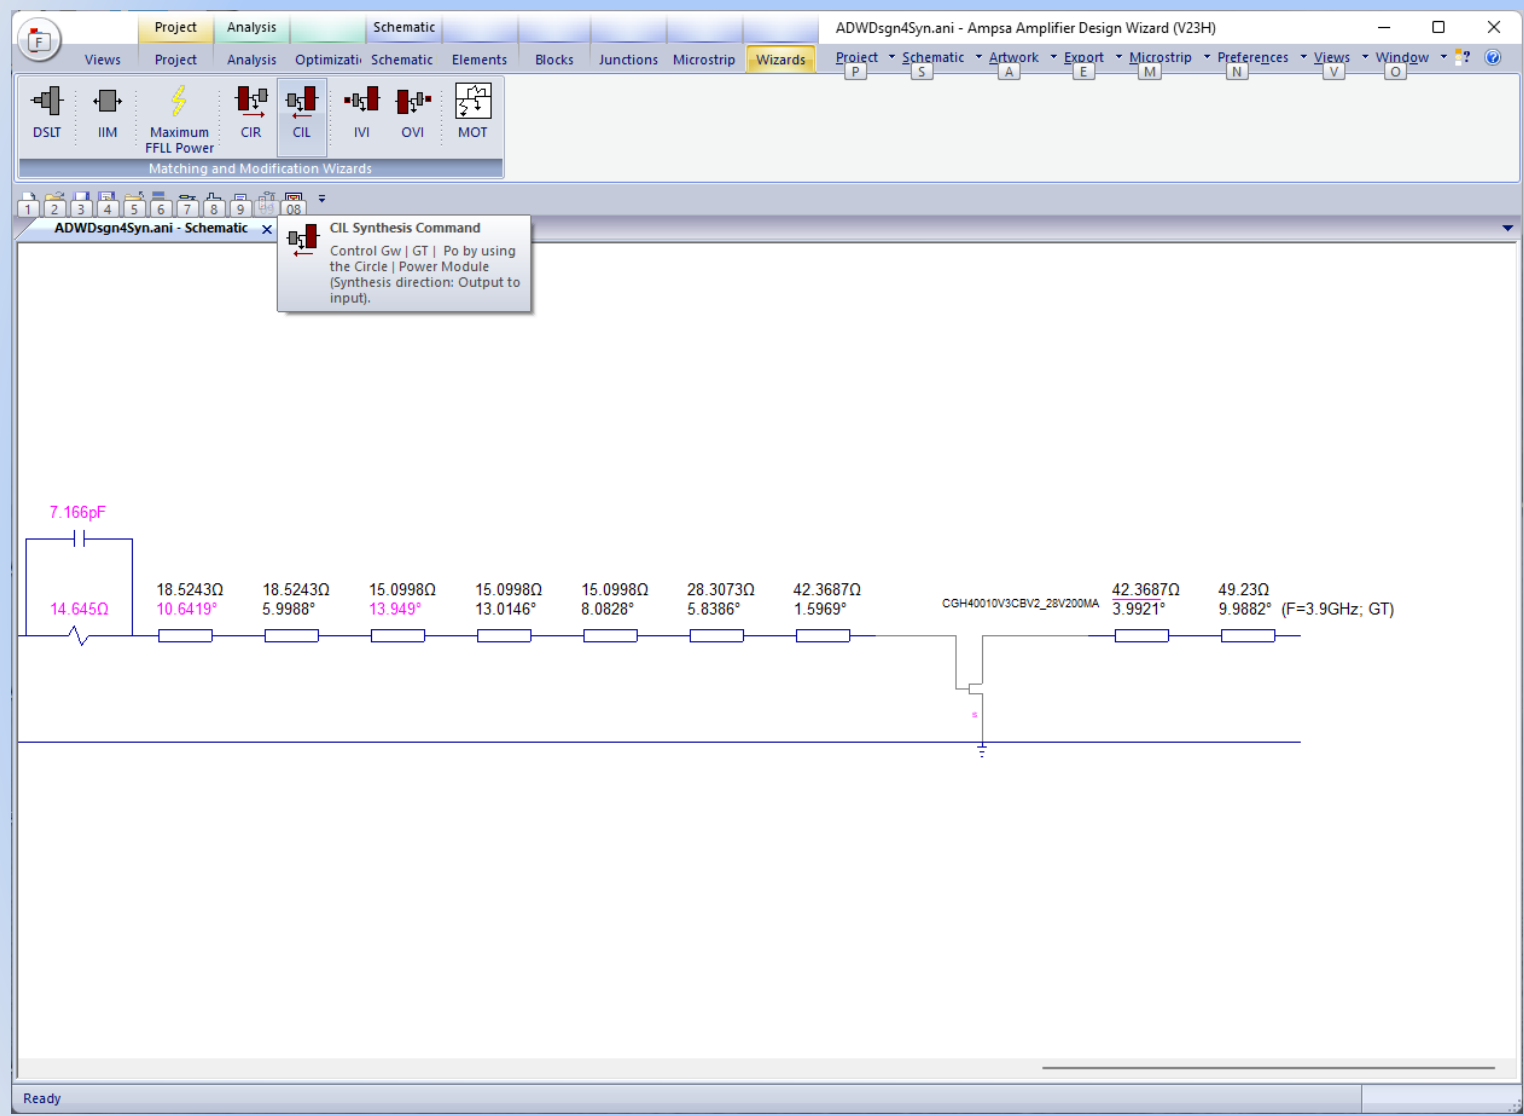

In this presentation, the CIL wizard will be used to setup the specifications for the load matching network of a 1.0 – 3.9 GHz 10W amplifier. Solutions to the defined problem will also be synthesized by using the impedance-matching wizard provided in the ADW.

The Macom CGH40010F GaN transistor will be used in this example. An ADW model was fitted to the transistor biased at 28V 200mA (Class-AB operation). Class-B operation will be targeted in this presentation, but the same design flow can be used for other classes of operation.

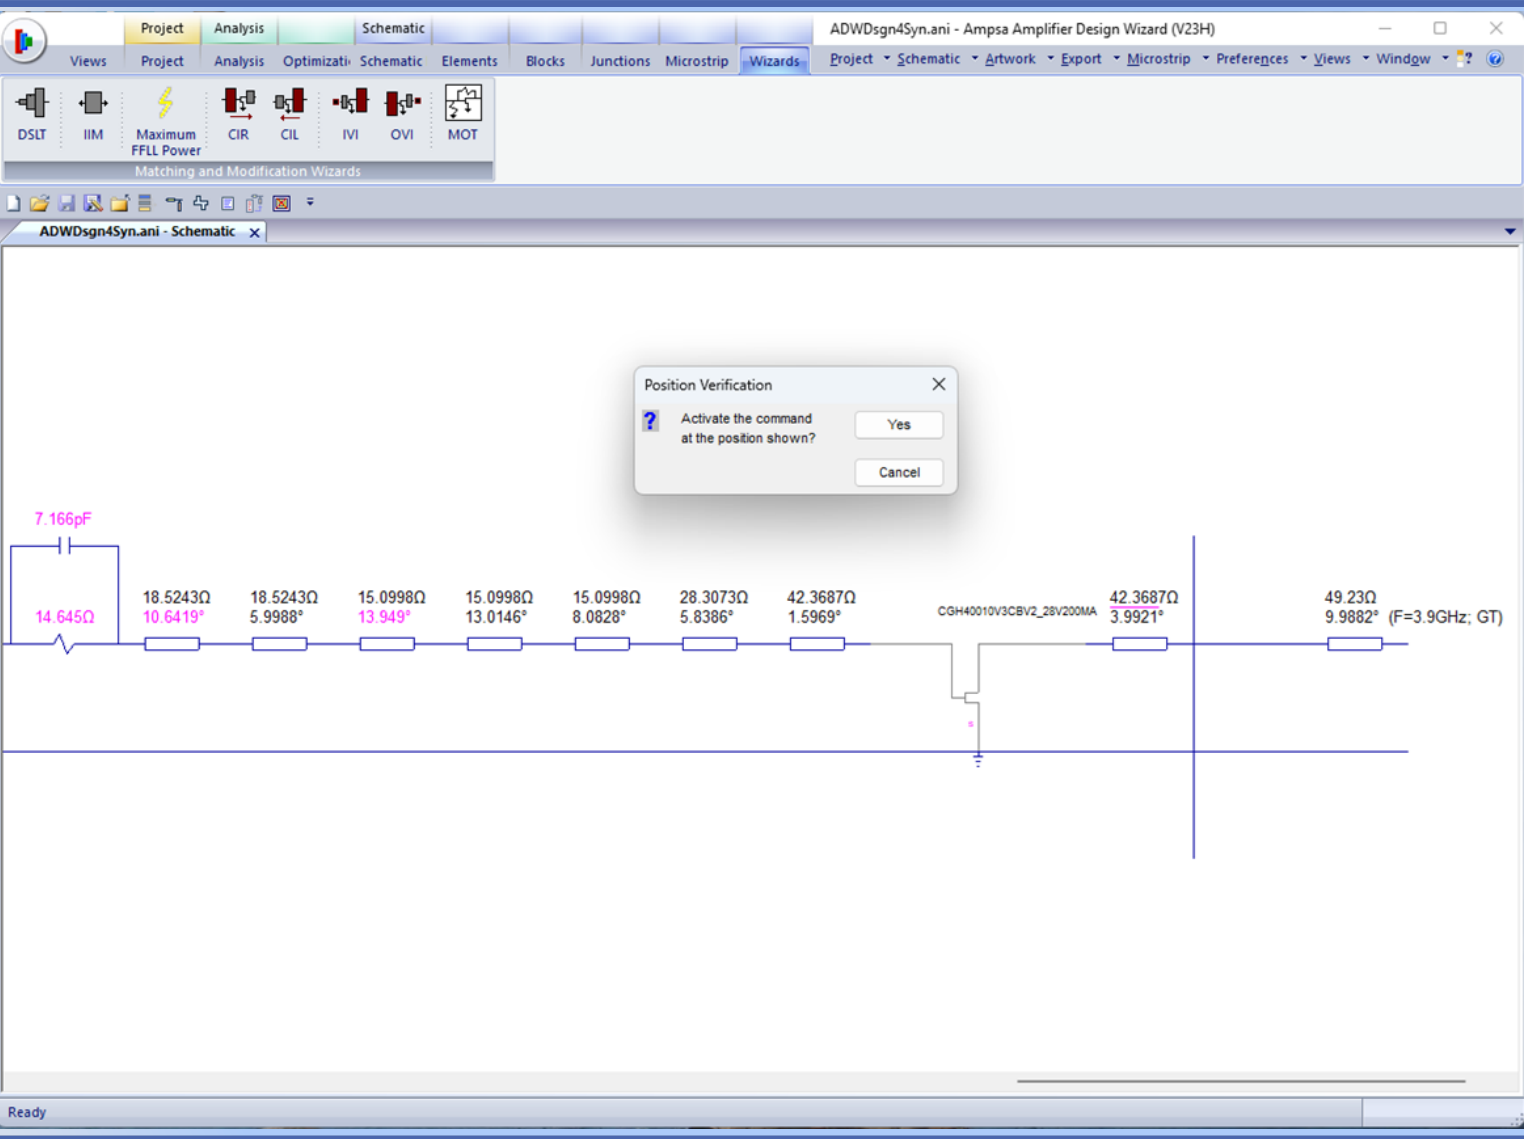

The circuit shown will be used as a starting point for the design. The input matching network is from a previous design, but the design flow is still valid without an input matching network in place. (Stabilizing the transistor, at least inside the passband is, however, advisable.) The input network can be optimised when the load network is in place.

Note that the schematic or the artwork or the text description of the circuit can be viewed. Use the commands provided on the quick access toolbar (QAT) to switch between views.

The ADW synthesis wizards must be launched with a schematic view active. The insertion point for the matching network required must be selected before launching the wizard.

Note that an element in the schematic is selected by left-clicking one of the labels associated with the schematic element. In an artwork view, the artwork element to be selected is left-clicked.

The CIL wizard was launched by selecting the Schematic | Wizards | CIL ribbon command. The schematic will be split as shown by the command.

The matching network to be designed with the CIL wizard can be the load network for the output stage or any driver stage in the amplifier. A multistage power amplifier is designed by starting with the load network.

ADWDsgn4Syn.ani - Schematic

CIL/CIR Impedance-Matching Wizard

Description

More control over the specifications of a matching network is possible when the CIL or CIR commands are used. The actual specifications are then decided in the ADW Power or Circle Module. The position of the network and the passband are set at this point, and the parameters required by the Power/Circle Module are calculated.

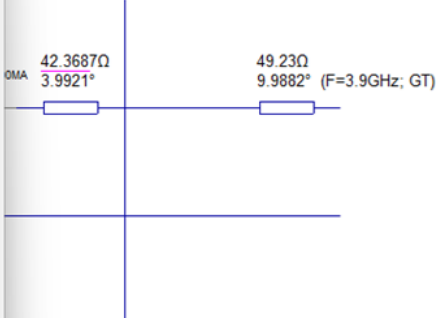

The CIL command is used when the design proceeds from the load towards the source, and vice versa for the CIR command. The output power, operating power gain or the transducer power gain can be controlled directly by using the CIL command. The CIR command is used to control the noise figure or the available power gain, and can also be used to control the transducer power gain.

49.23Ω  
9.9882° (F=3.9GHz; GT)

The first page of the CIL wizard is displayed here.

CIL/CIR Impedance-Matching Wizard - Contour Option

When the CIL command is used, the transducer power gain, the operating power gain or the output power of the stage selected can be controlled directly. The transducer power gain, the available power gain or the noise figure can be controlled directly when the CIR command is used.

Performance to be Controlled

- Operating power gain (Conjugate match required on the input side)
- Transducer power gain (Input matching network in place or not required)
- Output power

< Back   Next >   Cancel   Help

The operating power gain or the transducer power gain or the output power of the stage designed can be controlled by the CIL wizard. The option to control the power was selected here.

CIL/CIR Wizard - Power Module Options

When the power performance is controlled, the output power or the effective output power (Pout-Pin) can be specified. The gain calculated on the contours can also be specified to be the transducer power gain, or the available/operating power gain of the stage/section of interest (The transducer power gain option should be used when the input matching network is already in place). The option to specify the power termination or to specify the contours to be generated is also provided.

Power Option

Control the output power (Pout)  
 Control the effective output power (Pout-Pin)

Gain Control Option

Control Gw (Conjugate match required on the input side)  
 Control GT (Input matching network, if any, in place)

Specifications Option

Specify the external load  
 Specify the intrinsic load  
 Specify power contours

Impedance-Matching Option

Set ZLi as synthesis target

< Back   Next >   Cancel   Help

The output power or the effective output power can be controlled. Use the effective output power when the transistor gain is low or when a matching network for an oscillator is designed.

When an input matching network is already in place, the gain to be controlled is the transducer power gain. This option was selected here.

The power contours option was selected here. The alternatives are to control the intrinsic or external load terminations directly.

Note the option to use the intrinsic load terminations as synthesis targets. When this option is not selected, the input terminations presented by the matching network at the insertion point are used as targets.

CIL/CIR Wizard - Power Specifications

The maximum unclipped power (dBm) required at each frequency must be specified below. The power specified must be less or equal to the maximum power. Two additional contours can also be displayed graphically. Use the error function weights and zero error points commands to define the error function used to decide the default optimum point on each power contour targeted.

Efficiency Fitting Factor: 0.000 <0.0> [0.0: 0.1]

The power levels of interest must be specified on this page. Constant power contours can also be generated at two additional power levels at each frequency.

The error function used to select the optimum point on each contour is set by using the Error Function Weights and Zero Error Points commands.

Edit Relative or Edit Absolute are used to set the contour power levels.

The efficiency associated with the peak power points and the maximum efficiency associated with the contours targeted are also listed in the table.

Note that the minimum acceptable efficiency must be specified for the efficiency lines to be displayed. (With the exception of a Class-A stage, the efficiency will vary on the circumference of each power contour.)

The constant power contours targeted are shown here with the maximum efficiency lines.

The intrinsic load impedance is purely resistive at the maximum efficiency point on a power contour. This point is located on the voltage clipping side of the power contour.

Note the anti-clockwise rotation of the maximum efficiency lines with increasing frequency (green to magenta). Also note the area in which all the constant power contours intersect and the area in which the maximum efficiency lines intersect.

The constant power contours and the efficiency lines at 1.0 GHz and 3.9 GHz are displayed here.

Three efficiency lines are shown with the power contours at each frequency. The two lines away from the maximum efficiency line are constant efficiency lines.

Efficiencies above the targeted level can only be obtained on the contour sections defined by the two constant efficiency lines.

The performance on the circumference of a constant power contour is listed here (select the frequency of interest from the list provided). The optimum point selected on the contour is high-lighted and can be changed.

A circle (fundamental frequency targets) can be fitted automatically to each contour or the optimum point on each contour for impedance-matching purposes.

The option to target circles centred on the optimum point of each contours was selected here. The area inside each of these circles will be targeted.

Phase Control Help

< Back Next > Cancel Help

The performance at the optimum point on each power contour is listed on this page.

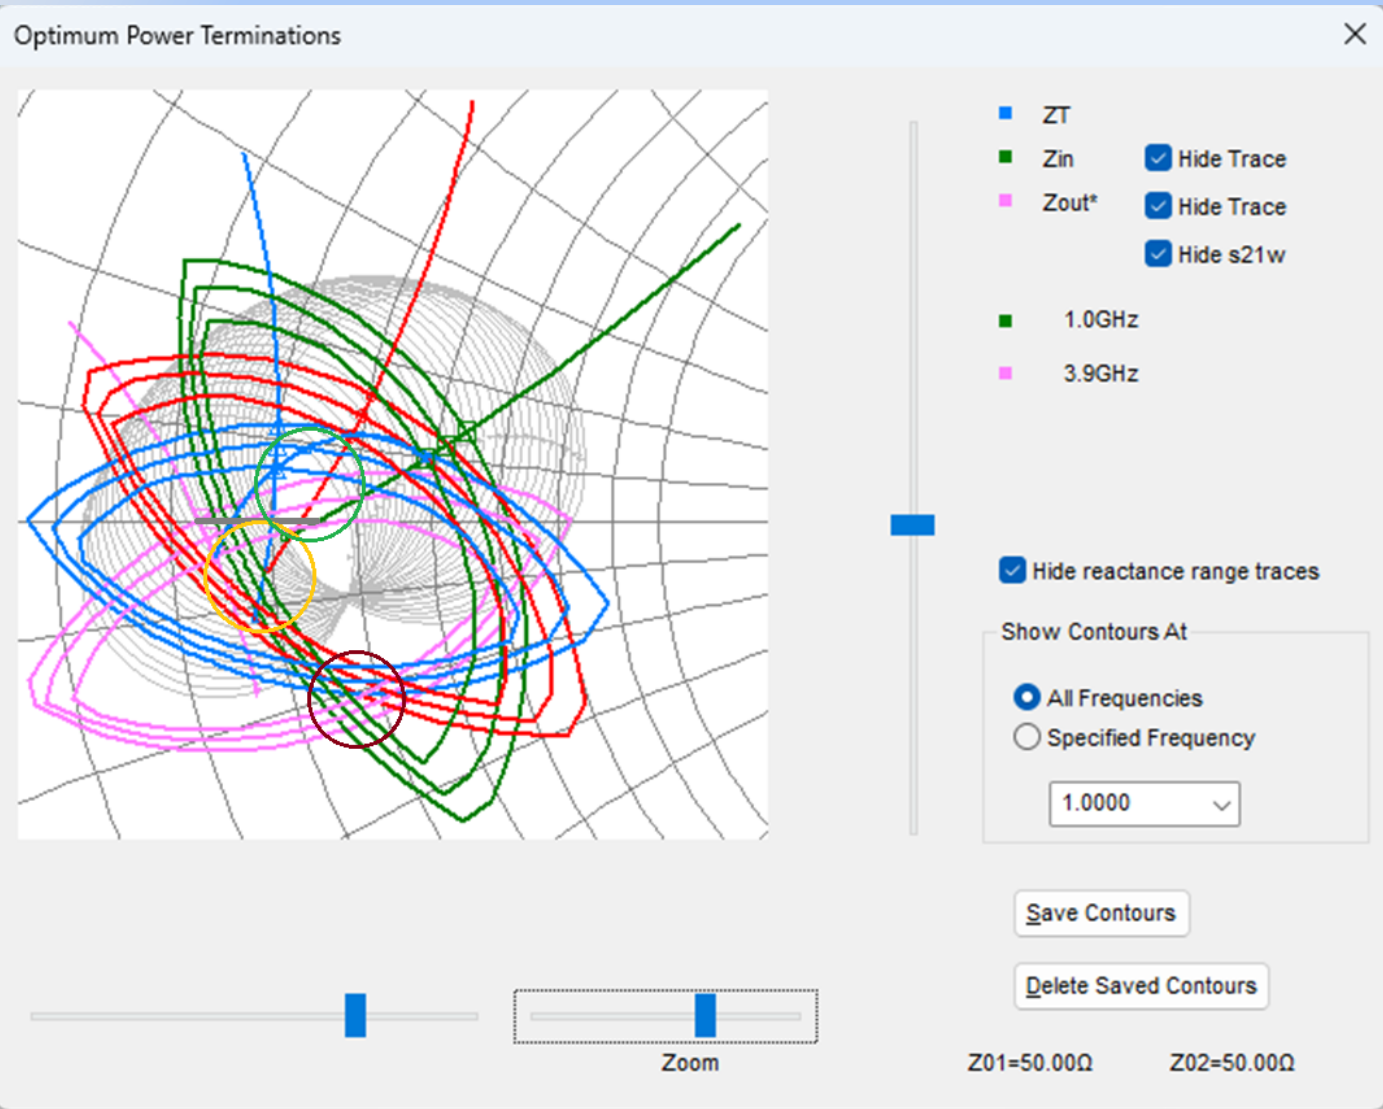

The Set Harmonic ZL and Set Harmonic ZL (Asymmetrical) commands can be used to set impedance-matching targets for the harmonic terminations. Class-B operation will be targeted here.

Note the Harmonic Traps command. Harmonic traps can be added to the matching networks to be synthesized as fixed elements by using this command. The option to export the traps selected directly to the circuit file is also provided.

The Explore Pre-Match option (CMA networks) provides an alternative to the Impedance-Matching module. The transmission phase-shift can be controlled directly by using this option (The CMA networks are derived from PI-networks and T-networks; two cascaded lines are also allowed). The intrinsic load terminations cannot yet be controlled directly by using this option.

The pre-match option will not be used in the presentation.

The Display Graph command provided on the wizard page was used to display the circles to be targeted in the Impedance-matching module. The constant power contours and the maximum efficiency lines are also shown.

Note that the origins of the maximum efficiency lines are located in a relatively small area. This area can be targeted by targeting power levels close to the peak levels. A good alternative is to target the line segment defined by the intersects of the maximum efficiency lines with the zero reactance line. This can be done by using a segmented taper transmission line.

Also note the eye formed by the circles targeted here. This area could also be targeted.

Power close to the targeted levels can be obtained at all of the frequencies shown by targeting the red circle at the bottom of the plot. The efficiency will, however, be lower that the level targeted.

Phase Control Help

Navigation: < Back, Next >, Cancel, Help

The performance at the optimum point on each power contour is listed in the table shown.

The intrinsic load impedance targeted is around 31.9 Ohm. The impedance required at the insertion point for the matching network is around 29 Ohm and lower (see the next slide). Take note of these levels. When the matching networks synthesized do not allow for biasing the transistor, fixed components can be added to the matching network. Any extra shunt elements added should ideally present impedances significantly higher than the impedances targeted (say, at least three to four times higher).

### Harmonic Control Specifications

**2nd Harmonic (H2)**

Control 2nd harmonic terminations  
 $ZF_{2ndH}: 2.50$   
 RangeScaFac:  $1.000$  [0.01; 1.0]  
 AsymSpecs:  $0.000$  <0>  
 Minimum intrinsic Q:  $5.00$   
 Width of the H2 transition band:  $0.10000$  GHz

Low second-harmonic impedance  $ZLi_{2ndH} = j ZLi_{Fund} / ZF_{2ndH}$   
 High second-harmonic impedance  $ZLi_{2ndH} = j ZLi_{Fund} \times ZF_{2ndH}$

**3rd Harmonic (H3)**

Control 3rd harmonic terminations  
 $ZF_{3rdH}: 2.50$   
 RangeScaFac:  $1.000$  [0.01; 1.0]  
 AsymSpecs:  $0.000$  <0>  
 Minimum intrinsic Q:  $5.00$   
 Width of the H3 transition band:  $0.10000$  GHz

High third-harmonic impedance  $ZLi_{3rdH} = j ZLi_{Fund} \times ZF_{3rdH}$   
 Low third-harmonic impedance  $ZLi_{3rdH} = j ZLi_{Fund} / ZF_{3rdH}$

### Fundamental-Frequency Terminations

Use RLi\_opt  
 RLi\_opt scale factor:  $1.000$  [0.75; 1.75]

Use saved ZLi  
 ZLi scale factor:  $1.000$  [0.75; 1.75]

Clipping Contour Option  
 Use H2 clipping contours  
 Reduce the assumed dc voltage by using the boundary line intercept  
 Correction voltage scale factor:  $0.500$  <0.5> [0; 0.95]

The Set Harmonic  $Z_L$  command was selected.

Low or high impedance second or third harmonic intrinsic terminations can be targeted. Because Class-B operation is required, low harmonic impedances will be targeted (low relative to the fundamental-frequency impedances).

Harmonic Control Specifications

**2nd Harmonic (H2)**

Control 2nd harmonic terminations

Low second-harmonic impedance  
 $Z_{Li\_2ndH} = j Z_{Li\_Fund} / ZF\_2ndH$

High second-harmonic impedance  
 $Z_{Li\_2ndH} = j Z_{Li\_Fund} \times ZF\_2ndH$

Width of the H2 transition band:  GHz

**Clipping Contour Option**

Use H2 clipping contours

Reduce the assumed dc voltage by using the boundary line intercept

Correction voltage scale factor:  <0.5> [0; 0.95]

OK Cancel Help Reset Class

The second and third harmonic bands in this example overlap the passband. The third harmonic band also overlaps the second harmonic band. The fundamental targets override the harmonic targets in the ADW, while the second harmonic targets generally override the third harmonic targets.

Transition bands can be defined for the second harmonics and the third harmonics. 0.4 GHz will be used for the second harmonic and 0.1 GHz will be used for the third. Because shorts are required for both harmonic bands, the transition band for the third harmonic could be set to zero.

The fundamental-frequency and harmonic targets at the insertion point for the matching network.

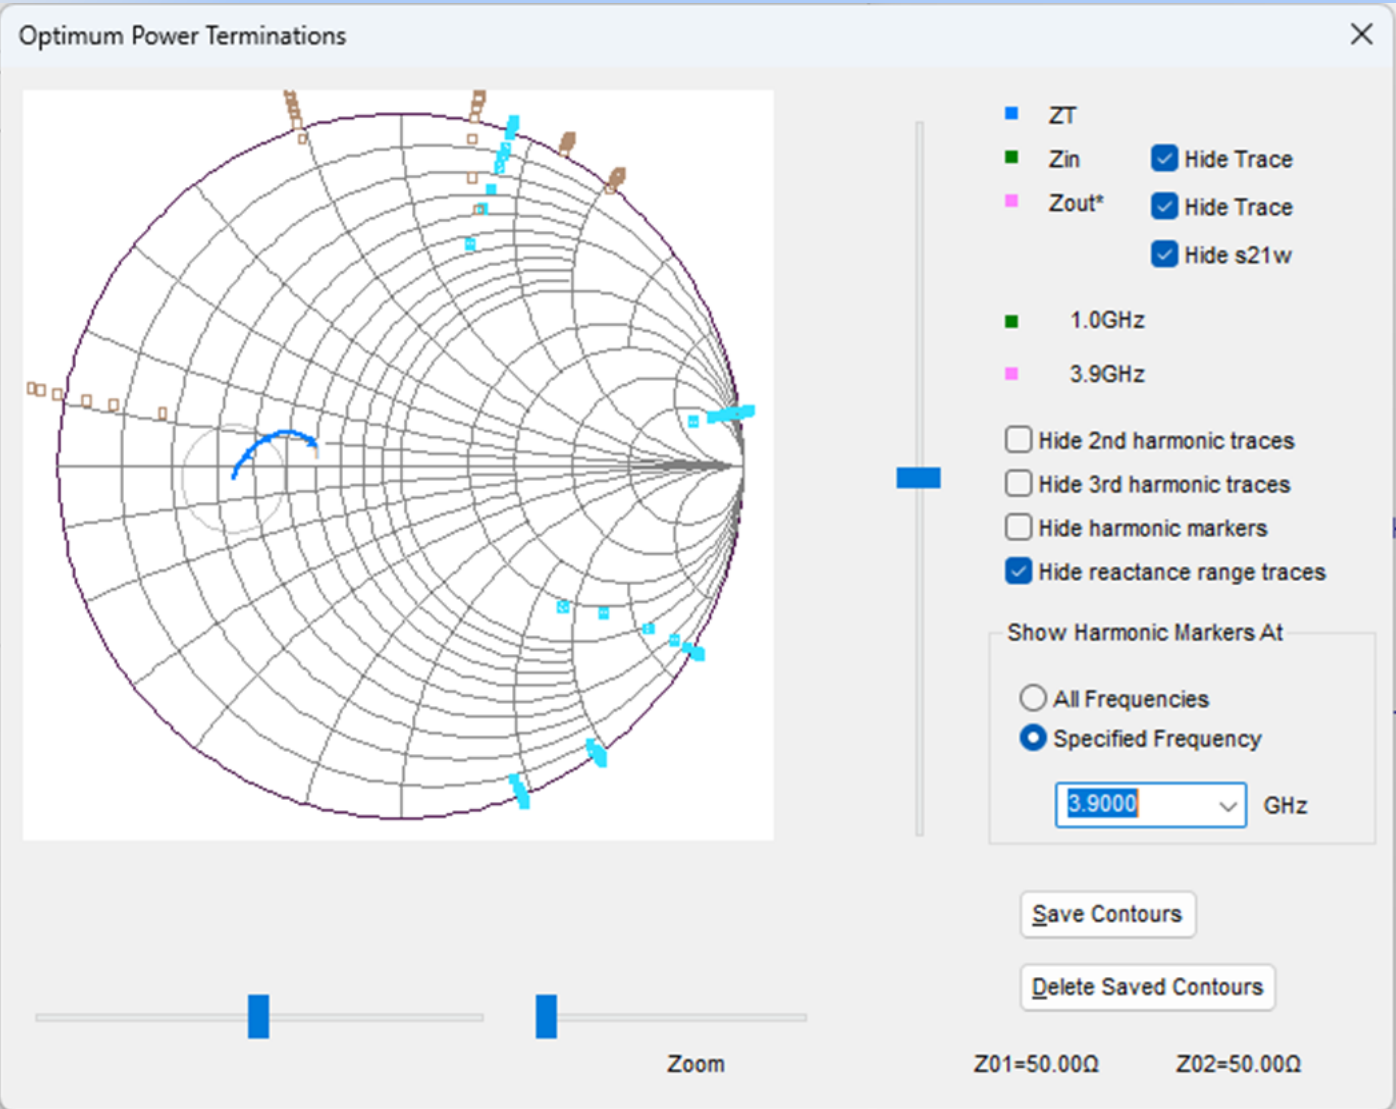

Options are provided to hide the third or the second harmonic targets.

The targets can be displayed for all the passband frequencies or for a specific passband frequency. The associated intrinsic impedances will be near shorts for terminations at the centre of the range of external reflection coefficients shown for each harmonic.

Harmonic sectors are fitted automatically to the areas defined by the harmonic markers. A sector is defined by a local origin and two intersects with the Smith chart edge.

Harmonic sectors will also be fitted to the intrinsic targets if the relevant option was selected.

The second and third harmonic targets associated with 3.9 GHz.

Note that the harmonic areas to be targeted rotate anti-clockwise with frequency. It will not be possible to obtain near shorts for all the harmonics with the passband targeted here.

**Z0SST:**       **Z0OST stepped line:**

(ML: Main line; OST: Open-ended stub; SST: Shorted stub.)

Target the optimum reactance with each trap      wcQs\_NoTraps: 0.22

Export selected traps to the circuit file      wcQL\_NoTraps: 0.00

Harmonic traps can be used to provide the required intrinsic impedance at specific frequencies. Potential traps are listed here for a number of second and third harmonic frequencies. When an SST option is set, the trap will be created with a shorted stub. The default is to use an open-ended stub.

When the series transmission line (ML) associated with a trap is short, the trap can be added to the circuit before a matching network is designed. Traps with longer main lines can be added on the output side of the matching network, but it is unlikely that the desired transmission phase shift required for an intrinsic short will be obtained with the matching network in place. The harmonic will, however, be filtered from the output.

Note that the traps marked with a P consist of a shorted stub in parallel with an open-ended stub.

Ideally a trap should not load the circuit significantly at the fundamental frequencies. The loading imposed is measured by calculating the worst-case fundamental-frequency source and load Qs, as well as the shunt reactance presented by the trap at a number of passband frequencies. The worst-case Qs of the terminations (no loading) are listed in the lower RHS corner of the table.

The trap with the shortest main-line length (18.285 degrees at 3.9GHz) is the 11.7 GHz trap. The loading associated with this trap will be minimal. Note that the H2\_P trap may be a good option for feeding in the drain bias. The shunt impedance presented is higher than 42.5 Ohm inside the passband (still significant).

Up to two traps can be selected from the table. The selected traps can be exported directly to the circuit file or can be added as fixed components to the matching networks to be synthesized.

The default name for the matching network file is shown here. The option to solve the matching problem with non-commensurate networks was selected.

CIL/CIR Impedance-Matching Wizard

You have successfully completed the steps of the CIL or CIR wizard. If the CMA command was used, or traps were selected for export, the associated schematic elements will be inserted into the circuit file next. If neither of these options were not chosen, the Impedance-Matching wizard will be launched next to solve the matching problem defined.

It is recommended that you save the circuit file after closing this wizard.

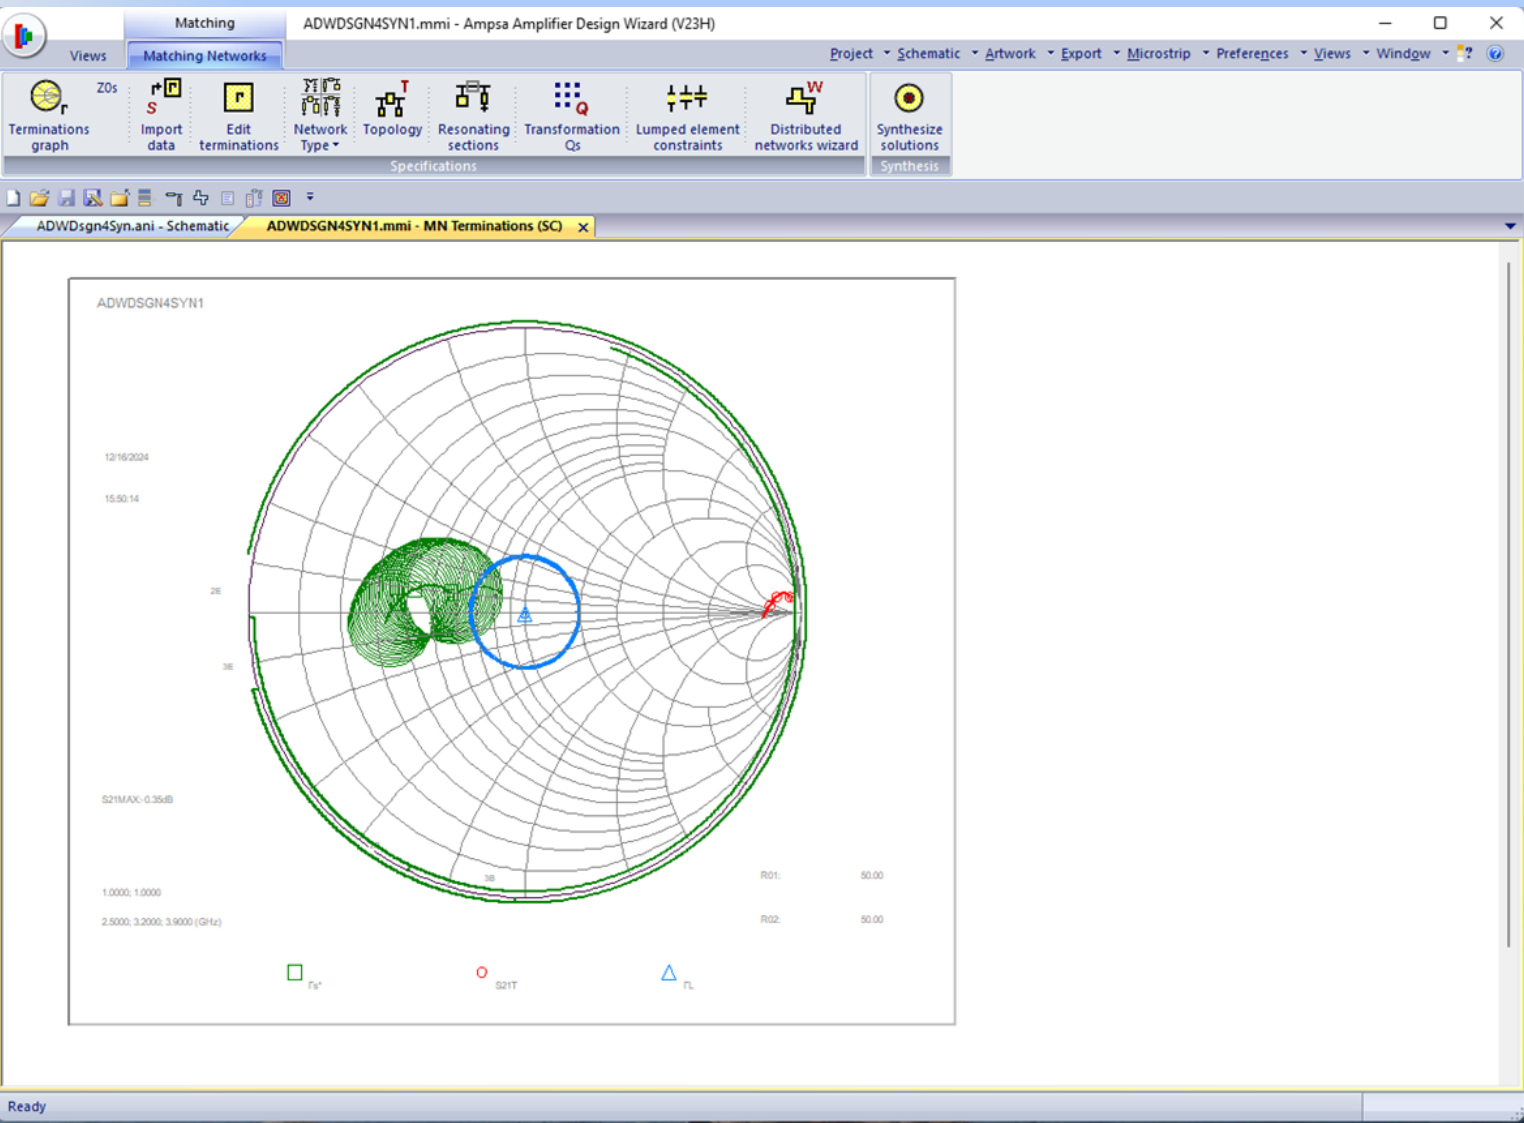

Save the circuit file automatically

C:\Users\USER\Documents\Ampsa\AmpsaADW23H\Examples\Power Amplifiers\Cree 10

Launch the Impedance-Matching Module

< Back Finish Cancel Help

The matching problem has been defined by the CIL wizard. The next step is to solve the problem.

The Matching wizard was launched and impedance-matching networks can now be synthesized.

Solutions to the matching problem will be synthesized next.

Ready

It is generally a good approach to try lumped solutions to a matching problem first (Use the Network Type ribbon command). Insight into the problem can be gained by doing this before proceeding to distributed solutions.

A lumped solution to the matching problem is shown here. The drain bias can be fed in through the inductor if the dc short is replaced with an RF short.

Use the Edit Terminations ribbon command and then select the 2<sup>nd</sup> Harmonic Targets command to change the transition band for the second harmonics.

The screenshot shows the Ampsa Amplifier Design Wizard (V23H) interface. The main window displays a Smith chart for ADWDSGN4SYN1. The chart has a green outer boundary and a blue inner boundary. A blue circle is drawn on the chart, and a red arrow points to a specific point on the chart. The chart is titled 'ADWDSGN4SYN1' and includes the following text: '12/18/2024 11:41:59', '2E', '3E', 'S21MAX: -0.35dB', '1.0000; 1.0000', '2.5000; 3.2000; 3.9000 (GHz)', 'R01: 50.00', and 'R02: 50.00'. A legend at the bottom of the chart shows a green square for  $\Gamma_{in}$ , a red circle for  $S_{21T}$ , and a blue triangle for  $\Gamma_L$ . A tooltip for the 'Distributed Network Wizard' is visible, with the text: 'Launch the wizard for setting up the specifications for the distributed/microstrip networks to be synthesized.' The software interface includes a ribbon with various tools like 'Terminations graph', 'Import data', 'Edit terminations', 'Network Type', 'Topology', 'Resonating sections', 'Transformation Qs', 'Lumped element constraints', 'Distributed networks wizard', and 'Synthesize solutions'. The status bar at the bottom left shows 'Ready'.

Distributed networks will be synthesized next.

The Distributed Networks Wizard is used to change the specifications for distributed networks. Use the ribbon command shown to launch the wizard. Any results views must be closed before the wizard can be launched.

Distributed/Microstrip Networks Wizard - Capacitor and Inductor Options

**Parasitic Components**  
The option to use shunt parallel-plate capacitors instead of open-ended stubs or shunt capacitors is provided here. The parasitic inductance or resonant frequency of any regular capacitors or the parasitic capacitance or resonant frequency to be used for any inductor in the matching network can also be specified here. The option to use shunt capacitors as harmonic traps is also provided.

**Parasitics**

Capacitor Inductance or Resonant Frequency

- Specify inductance (nH)
- Specify component resonant frequency (Fr\_GHz)
- Specify trap resonant frequency (FTr\_GHz) too

L\_nH: 0.000 nH      FTr\_GHz: \_\_\_\_\_ GHz

No parasitics for series capacitors

Inductance Capacitance or Resonant Frequency

- Specify capacitance (pF)
- Specify resonant frequency (GHz)

0.000 pF

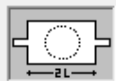

**Parallel-Plate Capacitors**

Use shunt parallel-plate capacitors

Pad width (um): 500.00      Pad length (L; um): 1.00E3

Pad Z0 (Ohm): 50.00      Pad length ("): 0.00

Via hole inductance: 0 nH

F = 3.900GHz

< Back   Next >   Cancel   Help

Parasitic inductance and capacitance can be specified for capacitors and inductors on this page.

The parasitic inductance or the resonant frequency for the capacitors can be specified. The option to use the shunt capacitors as harmonic traps is also provided.

Ideal lumped components will be used in this presentation.

Distributed/Microstrip Networks Wizard - Double Stub Options

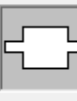

The option to use double stubs in the matching networks is provided here. If double stubs are allowed, they can be transformed to stepped main-line sections. This option is frequently used when power matching networks are synthesized.

Allow double stubs

Minimum electrical length (°) at which an open-ended stub should be converted to a double stub: 

0.00

Stepped main-line sections

Transform double stubs to stepped main-line sections 

Maximum width (um)	Minimum width (um)	Length (um)
0.00	0.00	0.00
Lowest Z0 (Ohm)	Highest Z0 (Ohm)	Electrical length (°)
25.00	65.00	30.00

F = 3.900GHz

Note: Not using resonating sections is usually a good option when open-ended stubs are replaced with stepped main-line sections (Allows short main-line sections).

< Back   Next >   Cancel   Help

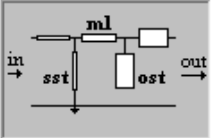

When it is possible, open-ended stubs in an ADW matching network can be transformed automatically to equivalent main-line sections.

A minimum electrical length can be set for the transformation.

The phase responses of the networks synthesized are generally better behaved when this is done.

Distributed/Microstrip Networks Wizard - Z0's

The characteristic impedance of the lines to be used are listed here. The line lengths will be used as variables. The minimum and maximum length to be used for the main line sections are listed too. The minimum length specification is important when stubs can overlap. When distributed networks are required, the characteristic impedances and line lengths should be modified on this page, if necessary. If the associated dimensions were specified previously for microstrip networks, the values listed should be inspected to ensure that the specifications made are realistic.

**Main-line Sections**

< Back    Next >    Cancel    Help

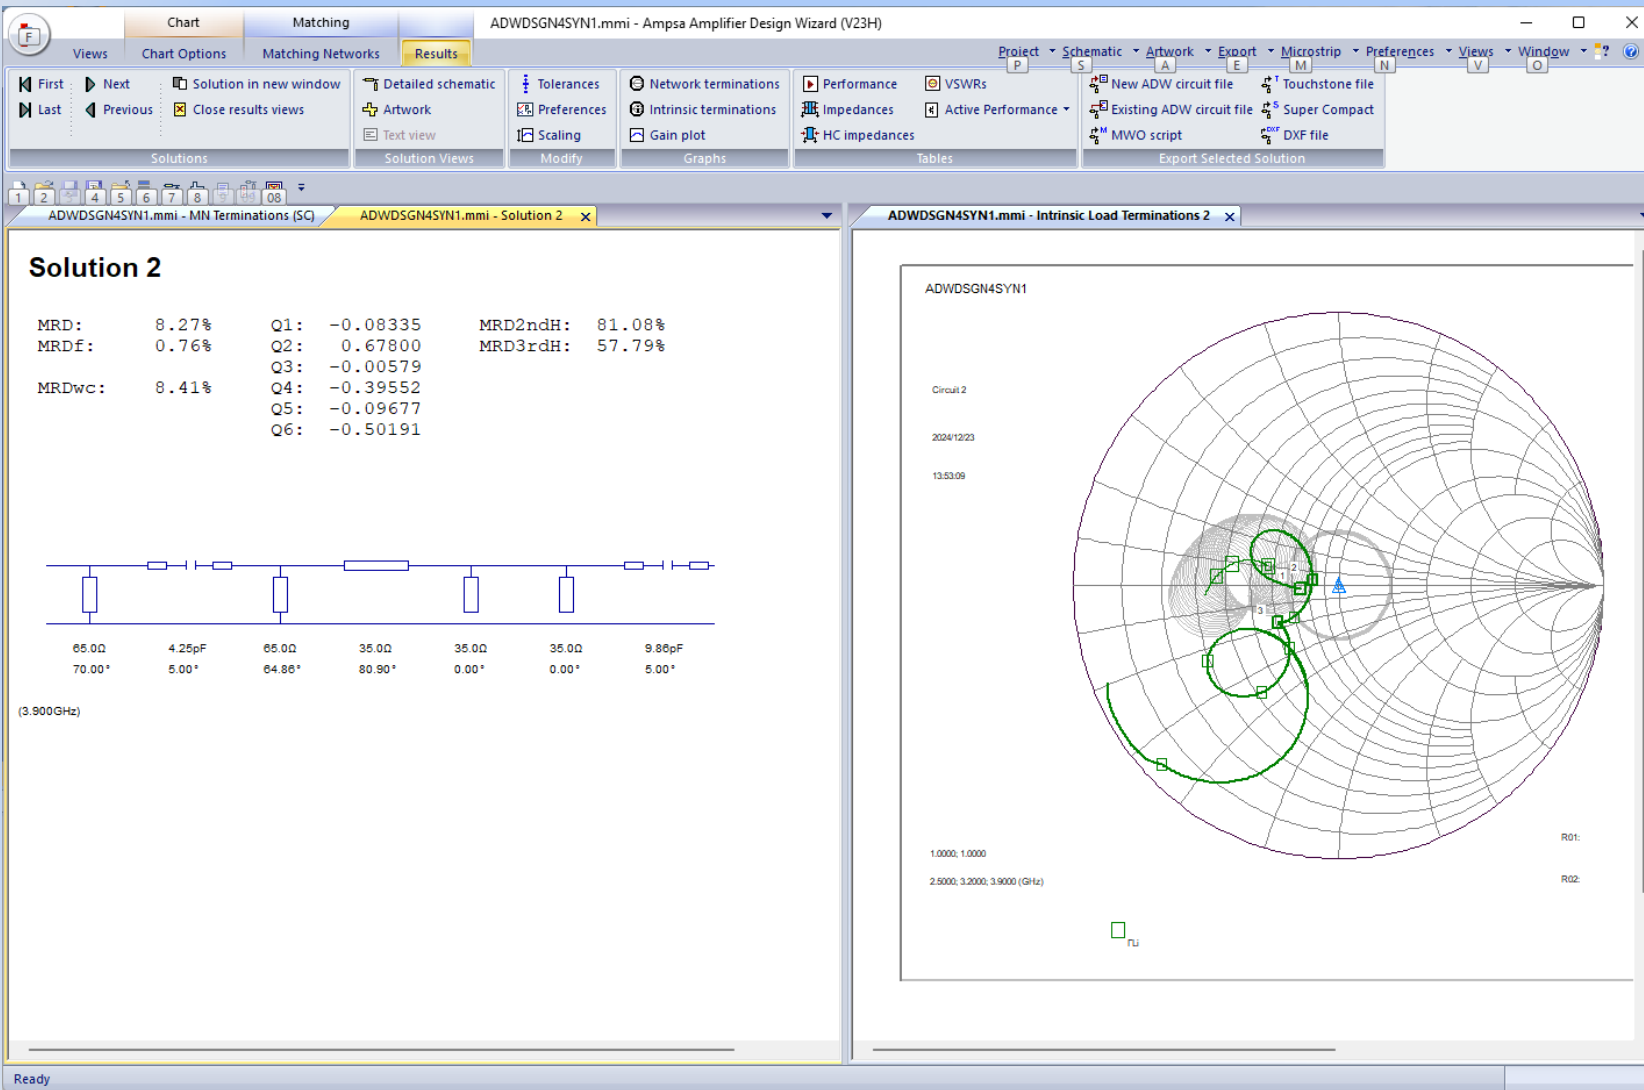

When the characteristic impedance specified for a stub allows it, the stub can be designed to provide a transmission null at a specified frequency in addition to providing the fundamental-frequency reactance required.

Different null frequencies can be set for the shorted stubs and the open-ended stubs.

If the option to transform the open-ended stubs to main-line sections was selected, the open-ended stubs will not be used to trap the harmonics.

Some experimentation with the trap frequencies is usually required. Start by setting the resonant frequencies to frequencies in the transition bands.

In this example, the transmission null frequencies were set to 11.0 GHz.

The second solution obtained with the specifications shown. Note that the absolute values of the transformation-Q associated with this solution is small (less than 0.68). Better solutions may be obtained by scaling the range of the systematic search done down.

Quick Edit

Ready

The range of the search was scaled down and the number of potential solutions to be used in secondary searches was increased.

The Transformation Qs ribbon command was used to open the dialog box shown.

To keep the run-time similar, the Q increment should be scaled by the same factor as the boundaries.

ADWDsgn4Syn.ani - Power and Efficiency Graph

ADWDsgn4Syn.ani - Intrinsic Load Terminations

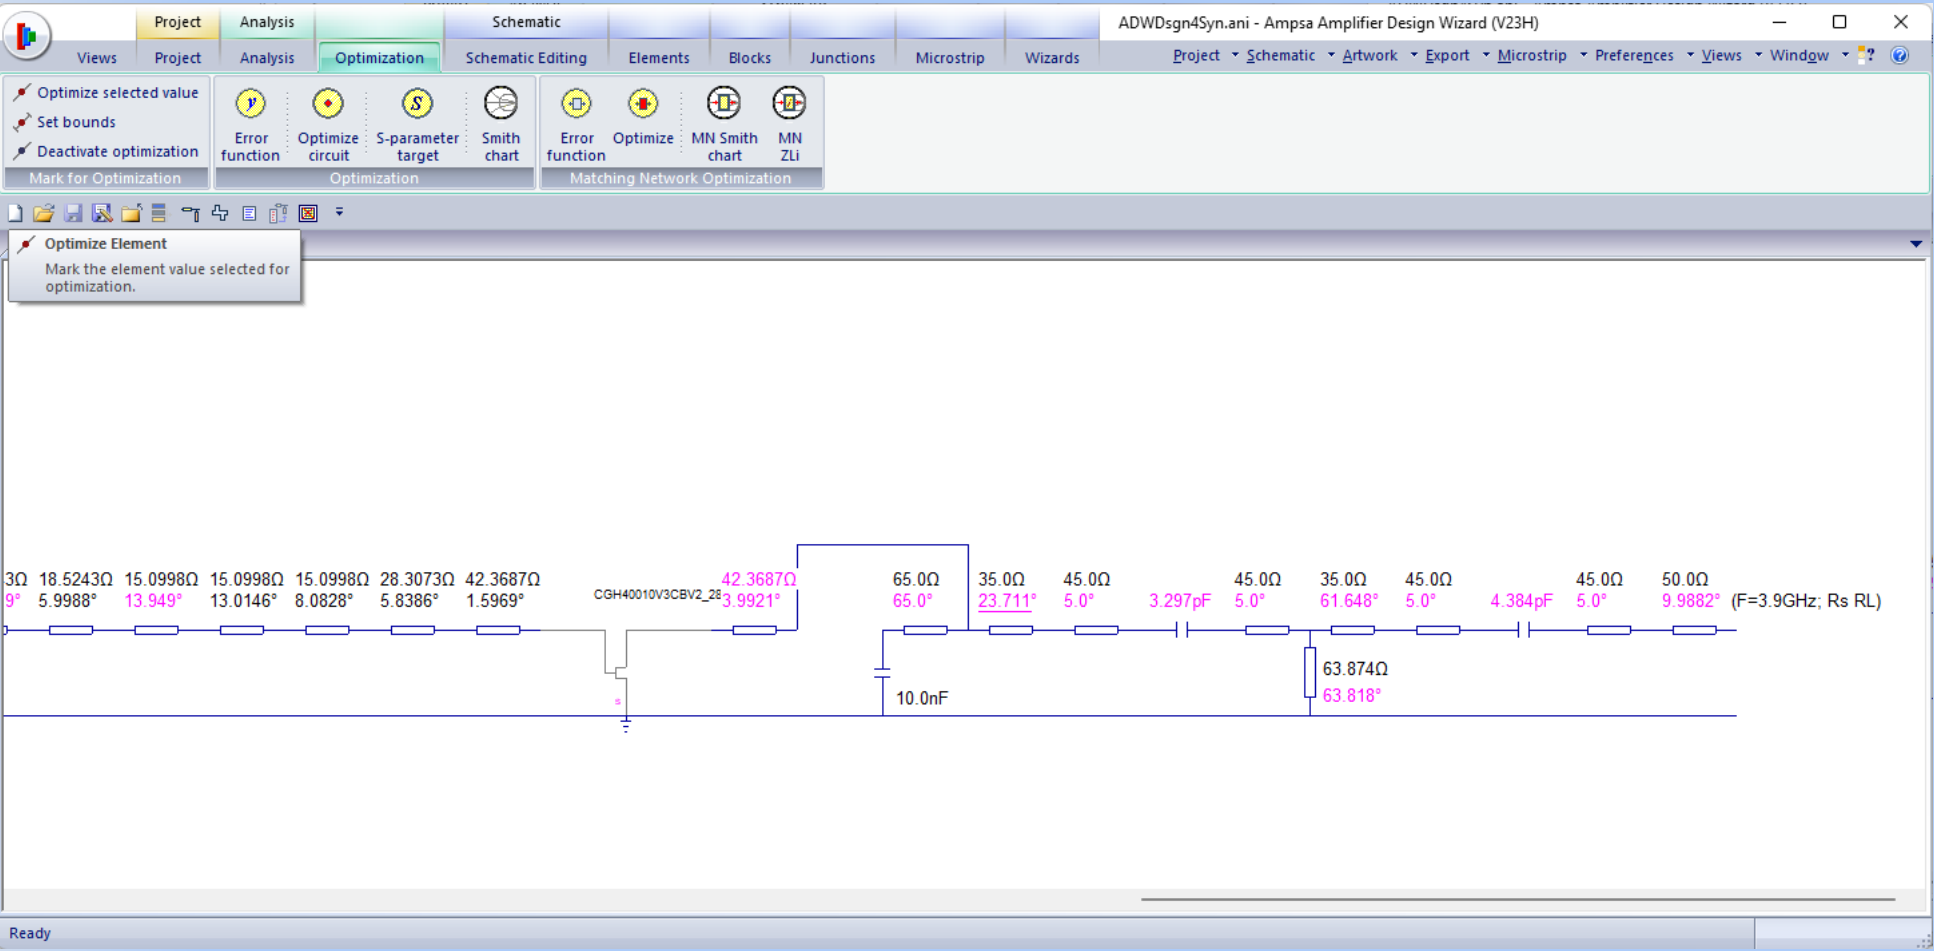

The performance obtained in the original circuit with the solution shown.

To allow for biasing the transistor, the schematic editing command shown will be used to convert the *dc* ground associated with the selected inductor to an *ac* ground.

The lumped-element parasitics were ignored when this matching network was synthesized. Parasitic elements can be added to a capacitor by using the command shown after selecting the capacitor. The capacitor value can then be tuned to compensate for the inductance added.

The performance of the matching network could also be improved by tuning or optimization. To tune the network, mark all the elements in the network for optimization first.

The command used to mark a variable for optimization is shown here. Note the Set Bounds command too.

If marked for optimization, the selected variable can be tuned after selecting the Analysis | Summary Table ribbon command.

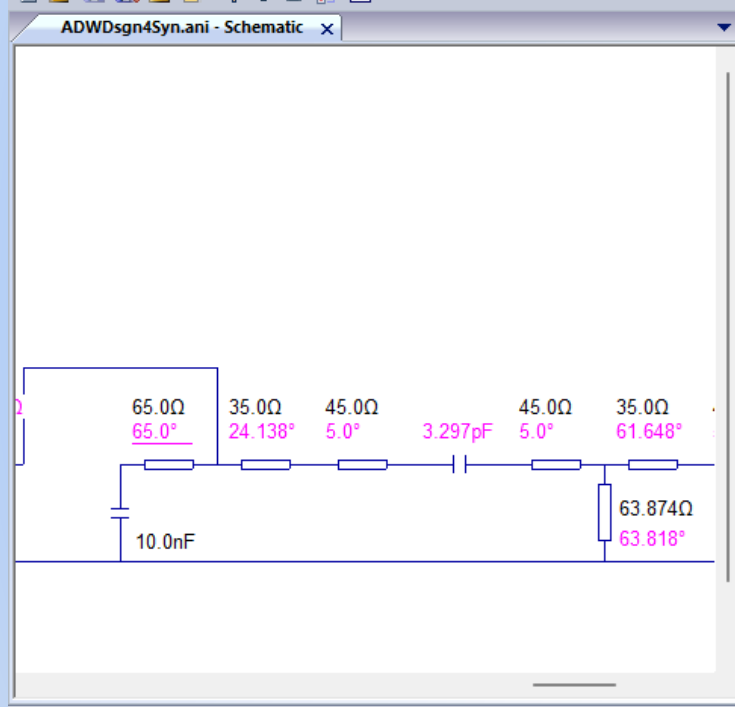

The circuit must be analysed before the element values can be tuned.
